

UCL

The neural basis of sign language processing

Mairéad MacSweeney

UCL Institute of Cognitive Neuroscience and
ESRC Deafness, Cognition and Language (DCAL) Research Centre

UCL

What do we know about neural basis of speech processing?

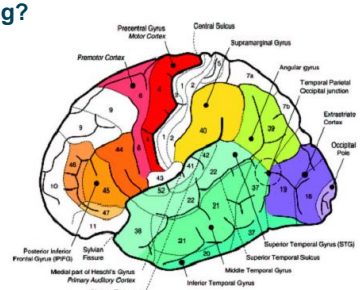

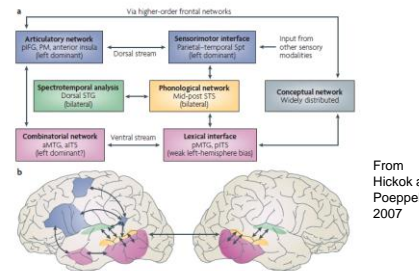

Image from Demonet et al., 2005

Many left hemisphere regions involved, in addition to so called 'Broca's' & 'Wernicke's' areas of the classical model

UCL

What do we know about neural basis of speech processing?

From Hickok and Poeppel, 2007

Figure 1 | The dual-stream model of the functional anatomy of language. a) Schematic diagram

Left hemisphere dominant for language in majority of people, but right hemisphere involved too ..

UCL

What do we know about neural basis of speech processing?

Medline search: brain AND speech = 15,603 papers

UCL

What do we know about neural basis of speech processing?

Medline search: brain AND speech = 15,603 papers

What do we know about neural basis of sign language processing?

Medline search: brain AND sign language = 362 papers

UCL

Do signed & spoken languages engage the same brain networks?

It depends on

<p>... what you compare sign language <i>with</i>:</p> <ul style="list-style-type: none"> auditory speech audio-visual speech silent speechreading reading 	<p>... and who you test:</p> <ul style="list-style-type: none"> stroke patients deaf native signers (~10% pop.) deaf non-native signers (~90% pop.) hearing native signers hearing late signers hearing non-signers
--	---

UCL

Do signed & spoken languages engage the same brain networks?

It depends on

<p>... what you compare sign language <i>with</i>:</p> <ul style="list-style-type: none"> auditory speech audio-visual speech silent speechreading reading 	<p>... and who you test:</p> <ul style="list-style-type: none"> stroke patients <i>But, predominantly late learners of SL</i>
--	---

UCL

Left hemisphere damage = sign aphasia

- evidence of impaired comprehension and production (depending on region)
- better on classifiers ('gestural') than prepositions ('linguistic')

Right hemisphere damage ≠ sign aphasia

- no evidence of impairment on standard language tests
- impaired processing of locatives (prepositions and classifiers). Due to visuo-spatial impairments?
- impaired on processing non-manual negation. Suggests may be prosodic.

(Atkinson et al., 2004; 2005; Marshall et al., 2003; 2005; Hickok et al., 1996; Poizner et al., 1987)

UCL

Sakai et al., Brain, 2005

Japanese SL sentence comprehension > nonsense
(deaf & hearing native signers)

A
L

B

Japanese auditory sentence comprehension > nonsense
(hearing non-signers)

UCL

BSL > baseline BSL sentences > single signs BSL > Tictac

A left-lateralised language network is recruited during syntactic & semantic processing, regardless of language modality.

UCL

BSL > baseline BSL sentences > single signs BSL > Tictac

A left-lateralised language network is recruited during sentence processing, regardless of language modality.

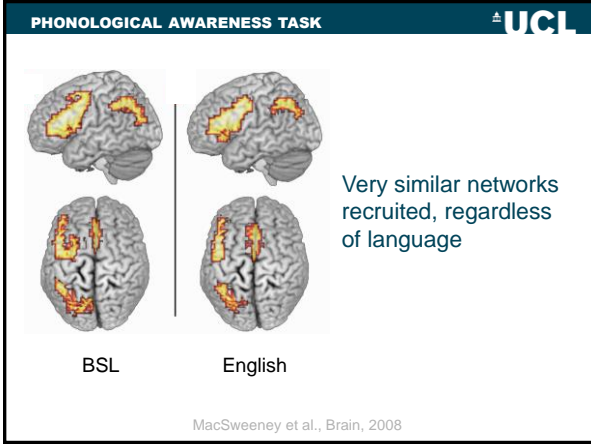

What about a metalinguistic task at the level 'closest' to sensory input - phonology?

PHONOLOGICAL AWARENESS TASK

English **BSL** **Control**

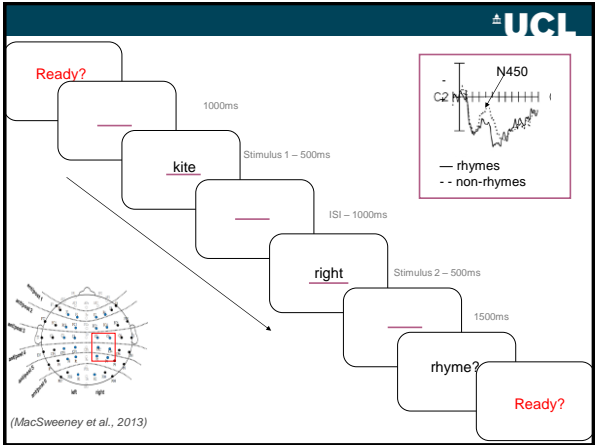

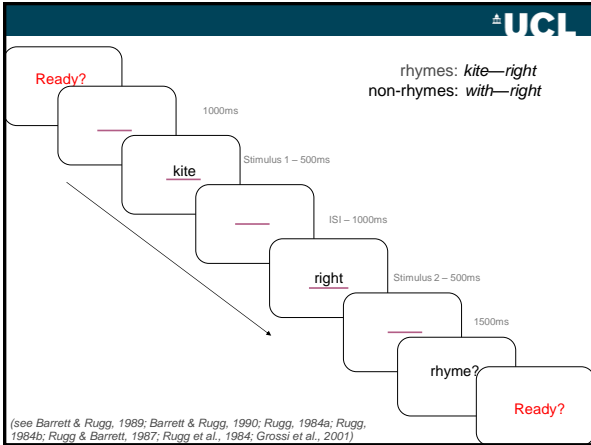

rhyme? rhyme? same?

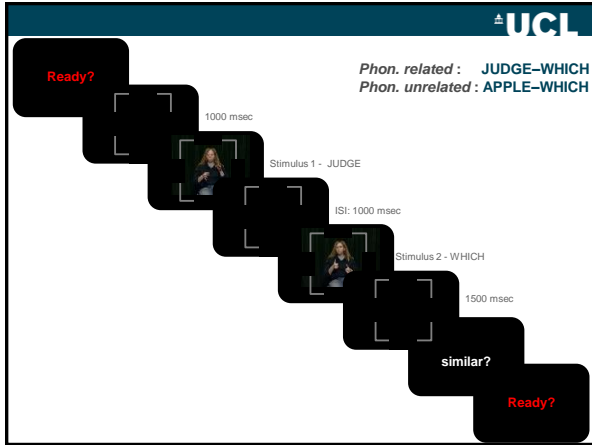

rhyme? location? same?

UCL

Timing of sign and speech phonological processing is also similar

UCL

Is the 'core language network' specific to *auditory* language?

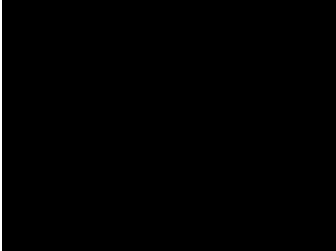

No

A left perisylvian network involved in language processing, regardless of modality

But the right hemisphere also plays a role - just as for spoken languages.

UCL

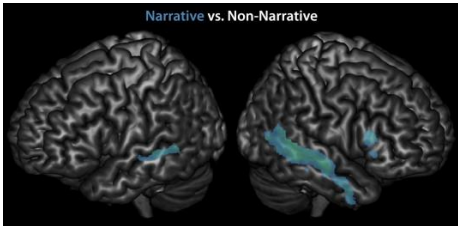

Contrast of 'narrative' and 'non-narrative' ASL sentences

Newman et al., Neuroimage 2010; Newman et al., PNAS, 2011

UCL

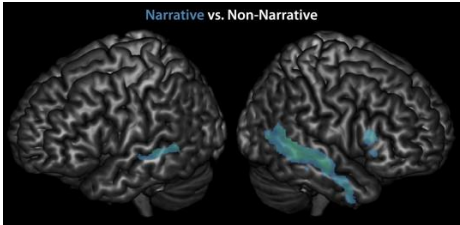

Narrative vs. Non-Narrative

Newman et al., Neuroimage 2010; Newman et al., PNAS, 2011

UCL

Narrative vs. Non-Narrative

Same contrast in audio-visual speech (with co-speech gesture) in hearing speakers ??

UCL

Do signed languages recruit the same neural systems as spoken languages?

Very similar.....but are not identical

sign ≠ speech

1. Differential engagement of sensory cortices
2. sign uses different articulators than speech (see - Capek et al., JOCN, 2008; Emmorey et al., 2007)
3. sign uses the face differently to speech (see Atkinson et al., Neuropsychologia, 2004)
4. Space can be used 'linguistically' in sign languages

UCL

A special role for parietal cortex in sign language processing?

(more than spoken language)

- stimulation of left inferior parietal lobe causes phonological production errors (Corina et al., 1999)
- greater left superior parietal lobe activation for memory for signs than words (Ronnberg et al., 2004)

UCL

Sign production uses different articulators than speech

Picture naming by hearing native signers
sign > speech

B.

from Emmorey, Grabowski et al 2007

UCL

PHONOLOGICAL AWARENESS TASK

BSL

English

Very similar networks recruited, regardless of language
... but not identical

Location?

rhyme?

UCL

MAIN EFFECT OF TASK: English V BSL

Region	English	BSL
Inferior frontal gyrus	~0.25	~0.10
Superior frontal gyrus	~0.25	~0.15
Superior parietal lobule	~0.05	~0.25

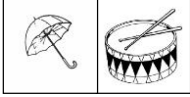

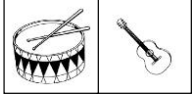

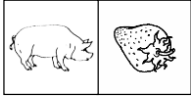

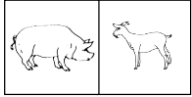

Growing evidence for a greater role of left parietal lobe in signed than spoken language processing

see Corina and Knapp, 2006; 2010; Emmorey, 2006; MacSweeney et al., 2008

UCL

Influence of sign phonological parameter on sign phonological judgments?

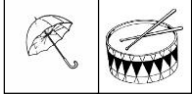

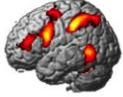

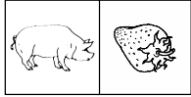

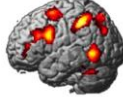

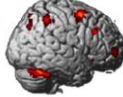

phonological task semantic task

	
handshape?	related?
	
location?	related?

UCL

Very little

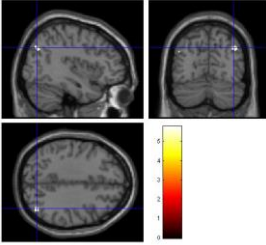

phonology > semantics

		
handshape?		
		
location?		

UCL

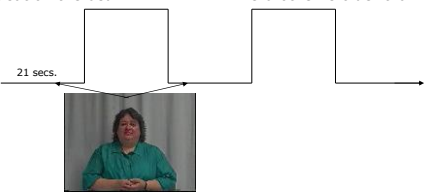

.... Only in right superior parietal lobe

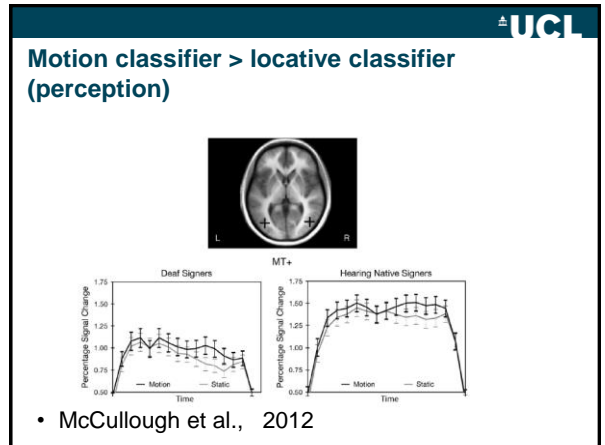

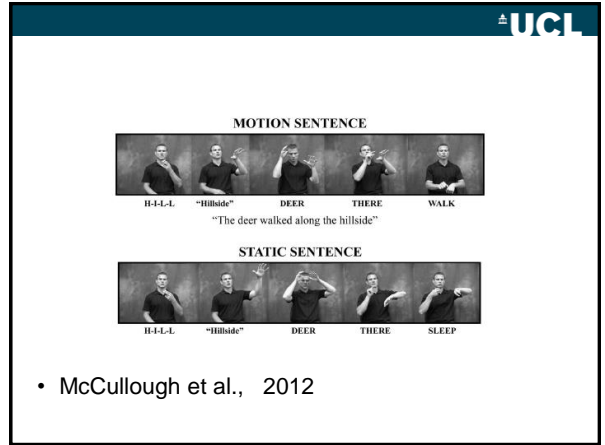

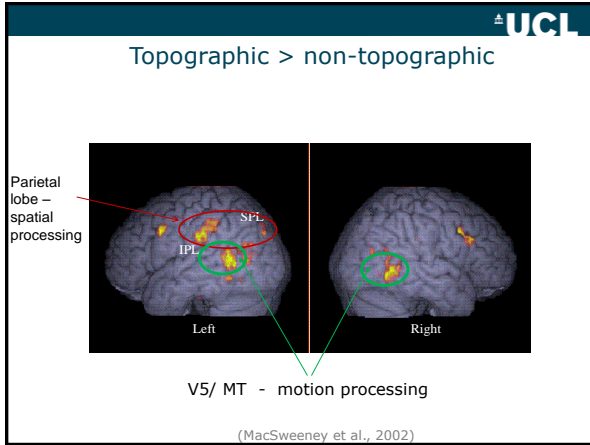

Location > handshape

UCL

The use of space in BSL

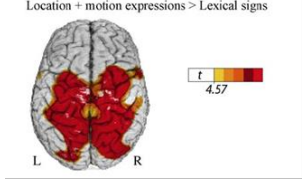

Topographic BSL sentences		Non-topographic BSL sentences	
	'The cat sat on the bed'		'The brother is older than the sister'
			
Baseline			

UCL

Classifier production

Location + motion expressions > Lexical signs

L R

Emmorey et al., 2013

UCL

What is the role of the inferior parietal lobe?

- known to play a role in perception, imagery of hand/finger movements (see Rizzolatti & Craighero, 2004)
 - therefore likely to play role in all aspects of sign language processing, especially sign language phonology

What is the role of the superior parietal lobule?

- Proposed to be involved in proprioception (Emmorey et al., 2007). However, no direct evidence for this yet.

UCL

Conclusions

- A left-lateralised network is recruited during language processing, regardless of modality.
- In addition - right hemisphere involved in *both* sign and speech processing
- networks very similar, but non-identical.
 - special role for left parietal lobe. Function not yet established

UCL

Conclusions

- A left-lateralised network is recruited during language processing, regardless of modality.
- In addition - right hemisphere involved in *both* sign and speech processing
- networks very similar, but non-identical.
- special role for left parietal lobe. Function not yet established

But does this inform theories of language processing or linguistic theory???

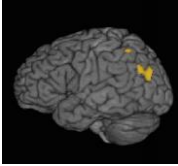

UCL

Saygin, et al., 2010 – audio-visual English sentences

static versus motion

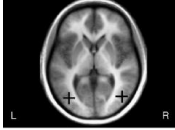

The deer slept on the hillside The deer walked up the hillside

parietal differences?

static > motion ASL sentences

MT differences?

Motion > static ASL sentences

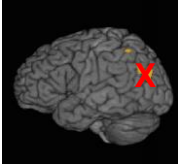

UCL

Saygin, et al., 2010 – audio-visual English sentences

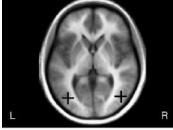

static versus motion

The deer slept on the hillside The deer walked up the hillside

parietal differences?

MT differences?

Yes

UCL

A cautionary note

UCL

Is there an influence of age of sign language acquisition?

It depends on who is tested ..

.

- hearing native signers
- hearing non-native signers

- deaf native signers (~10% pop.)
- deaf non-native signers (~90% pop.)

UCL

Is there an influence of age of sign language acquisition?

It depends on who is tested . . .

- hearing native signers
- hearing non-native signers

Newman et al., 2002 'A critical period for right hemisphere recruitment for ASL'
- right parietal lobe – native > non-native

- But, language backgrounds of hearing and deaf late signers are very different.

Not replicated with **deaf** native versus non-native signers.
(MacSweeney et al., 2008; Mayberry et al., 2011)

UCL

UCL

Synthesis – take home messages

- there is a CORE language network that supports both signed and spoken language.
 - this resides in the left perisylvian cortex
- additional 'satellite' regions – both sensory and non-sensory – support sign and speech. Some influenced by modality, others not
- the 'goal' is different for different researchers
 - to use language to learn more about the brain?
 - Or
 - to use the brain to learn more about language ?

Synthesis – questions

- does the brain care about linguistic versus non-linguistic divisions?
- can we actually test for 'amodal' language processing?
- what is the role of right hemisphere in language processing?
 - need 'parallel' studies in sign and speech
